Chapter 1

Introduction

1.1 Purpose

This document provides user-facing guidance for installing, configuring, and using System Monitor. It is intended for end users and system administrators.

1.2 Scope

This app, written in Rust to allow users to have fine grained control over their system processes and components across different Operating Systems. Users can view their system information, currently running processes and component performance including CPU, RAM and disk usage.

1.3 Goal

The goal of this project was to implement a cross platform replacement for task manager. This program can run on Linux, MacOS (Arm and x86) and Windows. Theoretically, this program should also run on Android and should anyone be willing to run this on their own device, please reach out [to my email](#) I would love to hear the results.

Chapter 2

Quick Start

2.1 Requirements

This program requires the Rust toolchain to install. When this project goes live on GitHub, I will include precompiled executables in the releases tab. Rust official install instructions are [available here](#) for any platform.

2.2 Installation

2.2.1 Build from source

```
1 # Clone and build (Rust)
2 $ cd final
3 $ cargo run
```

2.3 First Run

On `cargo run`, an executable can be found in the target folder. This executable can be used to run the program from any

Chapter 3

Using the Application

3.1 Overview of the UI

When the app launches, the home screen will be shown with a navigation bar at the top.

3.1.1 Pages

The following pages are shown in this version of the program.

- CPU Page: show current CPU usage, per-core graphs, history, and tooltip details.
- Memory Page: show RAM usage, swap, and breakdown if available.
- Disk Page: show partitions, free/used, IO activity.
- Process List: search, sort, inspect.
- From the file dropdown:
 - System Info: Misc. System info
 - Settings: explain configurable options and persistence.
 - About: version and credits.
 - Quit: exit program

3.1.2 Figure: Main Window

Chapter 4

Configuration

4.1 Settings

The settings selection in the **File** dropdown menu opens up a menu where settings can be configured and system operations can be completed. The first few settings are all functionality based. Collapsing same name processes will make it so similarly named processes will be combined to show usage by the entire application across threads and multiple PIDs. On supported systems, show CPU features will show hardware features supported by the CPU on the system info page. The theme of the entire application can be changed from the theme list. Below, system actions are placed to allow the user reset their system if need be.

Chapter 5

Troubleshooting

The command `cargo build` on Mac often struggles to find linked files. This will be addressed in future versions, for now, use `cargo run` to run the program. There is a known bug with `egui`'s plotting crate that combines graphs. This is shown when switching from the CPU usage to the main tab, where the overall CPU usage seems sporadic. We are using an older version of the crate for compatibility and when all crates are updated, hopefully this issue will be fixed.
